1 Introduction

This document presents the syntax and formal semantics of the Fiacre language. Fiacre is an acronym for Format Intermédiaire pour les Architectures de Composants Répartis Embarqués (Intermediate Format for the Architectures of Embedded Distributed Components). Fiacre is a formal intermediate model to represent both the behavioural and timing aspects of systems—in particular embedded and distributed systems—for formal verification and simulation purposes. Fiacre embeds the following notions:

- **Processes** describe the behaviour of sequential components. A process is defined by a set of control states, each associated with a piece of program built from deterministic constructs available in classical programming languages (assignments, if-then-else conditionals, while loops, and sequential compositions), nondeterministic constructs (nondeterministic choice and nondeterministic assignments), communication events on ports, and jumps to next state.

- **Components** describe the composition of processes, possibly in a hierarchical manner. A component is defined as a parallel composition of components and/or processes communicating through ports and shared variables. The notion of component also allows to restrict the access mode and visibility of shared variables and ports, to associate timing constraints with communications, and to define priority between communication events.

Fiacre was designed in the framework of projects dealing with model-driven engineering and gathering numerous partners, from both industry and academics. Therefore, Fiacre is designed both as the target language of model transformation engines from various models such as SDL or UML, and as the source language of compilers into the targeted verification toolboxes, namely CADP [8] and Tina [3] in the first step. In this document, we propose a textual syntax for Fiacre, the definition of a metamodel being a different task, out of the scope of this deliverable.

Fiacre was primarily inspired from two works, namely V-Cotre [4] and Ntif [7], as well as decades of research on concurrency theory and real-time systems theory. Its design started after a study of existing models for the representation of concurrent asynchronous (possibly timed) processes [5]. Its timing primitives are borrowed from Time Petri nets [11, 2]. The integration of time constraints and priorities into the language was in part inspired by the BIP framework [1]. Concerning compositions, Fiacre incorporates a parallel composition operator [9] and a notion of gate typing [6] which were previously adopted in E-Lotos [10] and LOTOS-NT [12, 13].

This document is organized as follows: Section 2 presents the concrete syntax of Fiacre processes, components, and programs. Section 3 presents the static semantics of Fiacre, namely the well-formedness and well-typing constraints. Finally, Section 4 presents the formal dynamic semantics of a Fiacre program, in terms of a timed state/transition graph.

2 Syntax

2.1 Notations

We describe the grammar of the Fiacre language using a variant of EBNF (Extended Bachus Naur Form). The EBNF describes a set of production rules of the form “symb ::= expr”, meaning that the nonterminal symbol symb represents anything that can be generated by the EBNF expression expr. An expression expr may be one of the following:
2.2 Lexical elements

IDENT ::= any sequence of letters, digits, or '_', beginning by a letter

NATURAL ::= any nonempty sequence of digits

INTEGER ::= [ '+', '-' ] NATURAL

DECIMAL ::= NATURAL [ '.' [ NATURAL ] ] | '.' NATURAL

*No upper bound is specified for the length of identifiers or numeric constants. The code generation pass will check that numeric constants can indeed be interpreted.*

Comments:

*Any sequence of characters between the symbol '/*' and the first following occurrence of the symbol '*/' is considered a comment.*

Reserved words and characters:

*Keywords may not be used as identifiers, these are:*

and any array bool channel component dequeue do else elsif empty end
enqueue enum false first from full if in init int interval is nat new
none not null of or out par port priority process queue read record select
shuffle states sync then to true type var where while write

The following characters and symbolic words are reserved:

```
[ ] ( ) { } : . . . = <> < > <= =>
+ - * / % $ | := ; ? ! -> /* */
```

4
2.3 Types and type declarations

type_id ::= IDENT
enum ::= IDENT
field ::= IDENT
size ::= NATURAL
type ::= bool | nat | int | interval INTEGER '..' INTEGER | enum enum+ end | record (field+ ':' type)+ end | array of size type | queue of size type | type_id
type_decl ::= type type_id is type

2.4 Values and expressions

var ::= IDENT

literal ::= NATURAL | true | false | enum | new NATURAL type

initializer ::= literal | '+' | '-' NATURAL | '[' initializer+ ']' | '{' (field '=' initializer)+ '}'

access ::= var | access '[' exp ']' | access '.' field

unop ::= '-' | '$' | not | full | empty | dequeue | first

infixop ::= or || and | '<=' | '<>' | '<' | '>' | '<=' | '>=' | '+' | '-' | '*' | '/' | '%'

Infix operators are listed in order of increasing precedence, those in same line have same precedence. All are left associative.
binop ::= enqueue

exp ::= literal
| access
| unop exp
| exp infixop exp
| binop '(' exp ',' exp ')'
| '(' exp ')' 

2.5 Ports, channels and channel declarations

port ::= IDENT

cchannel_id ::= IDENT

profile ::= none | type^+

channel ::= channel_id | profile | channel '|' channel

channel_decl ::= channel channel_id is channel

A port is a process communication point. Ports can be used to exchange data. A port type determines the type of data that can be exchanged on the port. Channels stand for port types. They have the structure of sets of profiles. Profiles specified by a series of types separated by '*' are associated with ports transferring several values simultaneously. Ports may have several profiles assigned, using channel operator '|'. A port having profile none may be used as a synchronization port (without any value transferred).

2.6 Processes

state ::= IDENT

tag ::= IDENT

name ::= IDENT

left ::= '[' DECIMAL
| ']'
| DECIMAL 'inf'

right ::= DECIMAL ']
| DECIMAL '
| inf ']'

left ::= time_interval ::= left ',' right

port_dec ::= ([in] [out] port)^+ ',' channel
Ports may have the optional in and/or out attributes, specifying that values may only be received and/or sent through that port. By default, ports have both the in and out attributes. The attributes apply only to the following port. When several ports are specified, all share the same channel but their attributes remain private.

\[
\text{arg} \text{ dec} ::= ([\text{read}] \ [\text{write}] \ \text{var})^+ \ ':Event' \ \text{type}
\]

Formal parameters have no attributes. Shared variables may have the read and/or the write attribute, specifying the operations that can be done on the variable. The attributes apply only to the following variable. When several variables are specified, all share the same type but their attributes remain private.

\[
\text{var} \text{ dec} ::= \text{var}^+ \ ':Event' \ [':=' \ \text{initializer}]
\]

All variables in the list share the same type and (optional) initial value.

\[
\text{process} \text{ decl} ::= \\
\text{process} \ \text{name} \\
\hspace{1em} [ '[\text{?}\ [\text{port} \text{ dec}^+ \ ':Event' ]'] ] \\
\hspace{1em} [ '[\text{?}\ [\text{arg} \text{ dec}^+ \ ':Event' ]'] ] \\
\hspace{1em} \text{is} \ \text{states} \ \text{state}^+ \ \text{init} \ \text{state} \\
\hspace{2em} [ \text{var} \ \text{var} \text{ dec}^+ ] \\
\hspace{2em} \text{transition}^+
\]

Name of the process, port parameters, functional parameters or references, states and initial state, local variables, followed by a series of transitions.

\[
\text{transition} ::= \text{from} \ \text{state} \ \text{statement}
\]

\[
\text{statement} ::= \\
\hspace{1em} \text{null} \\
\hspace{2em} | \text{access}^+ \ ':Event' \ \text{exp}^+
\hspace{2em} | \text{access}^+ \ ':Event' \ \text{any} \ [\text{where} \ \text{exp}] \\
\hspace{2em} | \text{communication} \\
\hspace{2em} | \text{while} \ \text{exp} \ \text{do} \ \text{statement} \ \text{end} \\
\hspace{2em} | \text{if} \ \text{exp} \ \text{then} \ \text{statement} \ (\text{elsif} \ \text{exp} \ \text{then} \ \text{statement})^* \ [\text{else} \ \text{statement}] \ \text{end} \\
\hspace{2em} | \text{select} \ \text{statement}^+ \ [\text{else}] \ \text{end} \\
\hspace{2em} | \text{to} \ \text{state} \\
\hspace{2em} | \ \text{statement} \ ':Event' \ \text{statement}
\]

Additional well-formedness constraints are given in Section 3.

\[
\text{communication} ::= \\
\hspace{1em} \text{port} \ [ ':Event' \ \text{profile} ] \\
\hspace{2em} | \text{port} \ [ ':Event' \ \text{profile} ] \ '?:' \ \text{var}^+ \ [\text{where} \ \text{exp}] \\
\hspace{2em} | \text{port} \ [ ':Event' \ \text{profile} ] \ '!:\text{exp}^+
\]

Synchronization over a port, or reception (?) or emission (!) of one or several values over a port. The optional profile constraint helps specifying the port referred to when it is overloaded.
2.7 Components

instance ::= name [ ']' port ] [ ')' ]

Instance of a process or component. Functional parameters are passed by value or by reference, according to the attributes of the corresponding formal parameters of the called component or process.

composition ::= shuffle composition+ end |
sync composition+ end |
par (port, '->', composition)+ end |
instance

More composition operators to be provided.

component_decl ::= component name

[ ']' port_dec+ ] |
[ ')' arg_dec+ ] |
is [ var var_dec+ ] |
[ port (port_dec [ in time_interval ])+ ] |
[ priority (port+ > port+)+ ] |
composition

Name of the component, port parameters, functional parameters or references, local variables or references, local ports with delay constraints, priority constraints, followed by a composition.

2.8 Programs

declaration ::= type_decl |
channel_decl |
process_decl |
component_decl

program ::= declaration+ name

The body of a program is specified as the name of a process or component. If that process or component admits parameters, then these parameters are parameters of the program.
3 Static semantics

3.1 Well-formed programs

3.1.1 Constraints

A program is well-formed if its constituents obey the following static semantic constraints.

1. Process and component identifiers should all be distinct;

2. Type and channel identifiers should all be distinct;

3. In any enum (resp. record) type, all values (resp. field labels) declared must be distinct;

4. In declarations of ports, formal parameters, or local variables, the identifiers declared must be distinct;

5. In a state declaration, all states must be distinct, and the initial state must be included;

6. There is a single syntactical class for shared variables, formal parameters of processes or components, local variables, and enum type components. As a consequence, the sets of global variable identifiers, formal parameter identifiers, local variable identifiers and enum component identifiers (declared globally or in the header of some process or component) should be pairwise disjoint;

7. No keyword (e.g. if, from, etc) may be used as the name of a component, process, variable, type, channel or port;

8. All variables, ports, states, referred to in a process or component must have been declared;

9. All enum components (resp. record labels) referred to in a process or component must appear in some enum (resp. record) type assigned to some declared variable or port of the process, or in the body of some type abbreviation;

10. In any interval type interval $x..y$, one must have $x \leq y$;

11. In a process, there may be at most one transition declared from each state declared after the state declaration;

12. In a delay declaration in a component, time intervals may not be empty (e.g. intervals like $[7, 3]$ or $[1, 1]$ are rejected);

13. In a priority declaration, the priority relation defined must induce a strict partial order;

14. In a deterministic assignment statement, the left hand side must have exactly the same number of components as the right hand side;

15. In an assignment statement, the access expressions in the left-hand side must be pairwise independent; that constraint is explained in Section 3.1.2;
16. In any transition, at most one communication statement may be found along any execution path and, along any path including a communication statement, no shared variable may be read or written. This constraint, referred to as the single-communication constraint is integrated with the well-typing condition for statements, see Section 3.2.5;

17. In any process, local variables or their constituents should be initialized before their first use, a sufficient static condition ensuring that property is discussed in Section 3.1.3;

18. In any component, all variables locally declared in the component must be statically initialized;

3.1.2 Well-formedness of assignment statements:

Left hand sides of assignment statements have the shape of series of access expressions. Each access expression is a sequence \( a_0 \ a_1 \ldots \ a_n \) where \( a_0 \) is some variable and each \( a_i \) (\( i > 0 \)) is either a field access (shape \( .f \)) or an array component access (shape \( [\exp] \)).

Two access expressions \( a_0 \ a_1 \ldots a_n \) and \( b_0 \ b_1 \ldots b_m \) are independent if:

- either \( a_0 \neq b_0 \)
- or for some \( i \) such that \( 0 \leq i \leq \min(n, m) \):
  - either \( a_i \) and \( b_i \) have shapes \( [x] \) and \( [y] \), respectively, where \( x \) and \( y \) are different integer constants;
  - or \( a_i \) and \( b_i \) have shapes \( .f \) and \( .g \), respectively, where \( f \) and \( g \) are different record labels.

3.1.3 Initialization of variables:

A static condition ensures that the variables locally declared in processes, or any of their constituents, are initialized before any use. The condition is similar to that used for the same purpose in the NTIF intermediate form, the reader is referred to [7] for details.

3.2 Well-typed programs

3.2.1 Type declarations, type expressions, types

Let us first distinguish type expressions from types: type expressions may contain user-defined type identifiers, while types may not. Type declarations introduce abbreviations (identifiers) for types or type expressions. With each type expression \( t \), one can clearly associate the type \( \tau \) obtained from it by recursively replacing type identifiers in \( t \) by the type expressions they abbreviate.

Similarly, we will make the same distinction between channel expressions (possibly containing channel identifiers) and channels. With each channel expression \( p \), one can associate the channel \( \pi \) obtained from it by replacing channel identifiers by the channels they abbreviate. Channels can be represented by sets of profiles.

All formal parameters of a process (ports or variables), and local variables, have statically assigned type or channel expressions, in the headers of the process, from which one can compute types or channels as above. By typing context, we mean in the sequel a map that associates:
• with each port, a set made of its attributes (a non empty subset of \{\text{in, out}\}) and profiles. Unless some attribute is made explicit in its declaration, a port has both \text{in} and \text{out} attributes;

• with each global variable, a set made of its attributes (a non empty subset of \{\text{read, write}\}) and type. There are no default attributes for variables;

• with each formal parameter, its type;

• with each local variable, its type.

Typing contexts are written \(A\) in the sequel, or \(A_b\) when referring to the context of some particular process \(b\). \(A(x)\) denotes the information (attributes and type(s)) assigned to variable (or port) \(x\) in \(A\).

### 3.2.2 Subtyping

Types (not type expressions) are partially ordered by a relation called subtyping, written \(\leq\) and defined by the following rules:

\[
\begin{align*}
\tau \in \{\text{bool, nat, int}\} & \quad (SU1) \\
\tau \leq \tau & \\
\text{nat} \leq \text{int} & \quad (SU2) \\
x \geq 0 & \quad (SU3) \\
\text{interval} \ x..y \leq \text{int} & \\
\text{interval} \ x_1..y_1 \leq \text{interval} \ x_2..y_2 & \quad (SU4) \\
\{c_1^1, \ldots, c_n^1\} \subseteq \{c_1^2, \ldots, c_m^2\} & \quad (SU6) \\
\text{enum} \ c_1^1, \ldots, c_n^1 \end & \leq \text{enum} \ c_1^2, \ldots, c_m^2 \end & \\
\text{array of} \ k \ \tau \leq \text{array of} \ k \ \tau' & \quad (SU7) \\
\text{queue of} \ k \ \tau \leq \text{queue of} \ k \ \tau' & \quad (SU8) \\
\{f_1, \ldots, f_n\} = \{g_1, \ldots, g_n\} & \quad (SU9) \\
\text{record} \ f_1 : \tau_1, \ldots, f_n : \tau_n \ \text{end} \leq \text{record} \ g_1 : \tau'_1, \ldots, g_n : \tau'_n \ \text{end} & \\
\end{align*}
\]

Note that \text{bool} and \text{nat} are not related by subtyping, nor are records with different sets of fields, or arrays or queues of different sizes.

Communication ports profiles are tuples of types. The subtyping relation is extended to profiles by:

\[
\text{none} \leq \text{none} & \quad (SU10) \\
\tau_1 \leq \tau'_1 & \quad \ldots \\
\tau_n \leq \tau'_n & \quad (SU11)
\]

### 3.2.3 Typing expressions

\(A\) is some typing context, the following rules define the typing relation (\(\cdot\)) for expressions.
Subsumption
\[ A \vdash E : \tau \quad \tau \leq \tau' \quad \frac{}{A \vdash E : \tau'} \] (ET1)

Literals, initializers
\[ K \in \text{INTEGER} \quad \frac{\text{Val}(K) = k}{A \vdash K : \text{interval } k..k} \] (ET2) \[ k \in \{\text{true}, \text{false}\} \quad \frac{}{A \vdash k : \text{bool}} \] (ET3) \[ c \in \text{Enums} \quad \frac{}{A \vdash c : \text{enum } c} \] (ET4)

\[ A \vdash k_1 : \tau \quad \ldots \quad A \vdash k_n : \tau \quad \frac{}{A \vdash [k_1, \ldots, k_n] : \text{array of } n \tau} \] (ET5)

\[ \{f_1, \ldots, f_n\} \subseteq \text{Fields} \quad A \vdash l_1 : \tau_1 \quad \ldots \quad A \vdash l_n : \tau_n \quad \frac{}{A \vdash \{f_1 : l_1, \ldots, f_n : l_n\} : \text{record } f_1 : \tau_1, \ldots, f_n : \tau_n} \] (ET7)

Enum is the set of all constants declared in enum types, Fields is the set of record field identifiers declared in record types. By abuse of notation, we write \( K \in \text{INTEGER} \) to mean that \( K \) belongs to the INTEGER lexical class. Function Val associates with a token in the INTEGER or NATURAL class the integer it denotes.

Primitives
\[ A \vdash x : \text{bool} \] (ET8) \[ A \vdash \text{not } x : \text{bool} \] (ET9)

\[ A \vdash x : \tau \quad \tau \leq \text{int} \quad \frac{}{A \vdash \neg x : \tau} \] (ET10) \[ A \vdash x : \tau \quad \tau' \leq \tau \leq \text{int} \quad \frac{}{A \vdash $x : \tau'} \] (ET11)

\$ is a coercion operator for numeric values. It converts a numeric value of some type \( \tau \leq \text{int} \) into a value of some subtype \( \tau' \) of \( \tau \). Conversion fails if the target value is out of range.

\[ A \vdash x : \tau \quad A \vdash y : \tau \quad \tau \leq \text{int} \quad \frac{}{A \vdash x @ y : \tau} \] (ET12)

\[ A \vdash x : \tau \quad A \vdash y : \tau \quad \tau \leq \text{int} \quad \frac{}{A \vdash x @ y : \text{bool}} \] (ET13)

\[ A \vdash x : \tau \quad A \vdash y : \tau \quad \frac{}{A \vdash x @ y : \text{bool}} \] (ET14)

\[ A \vdash q : \text{queue of } k \tau \quad A \vdash \text{empty } q : \text{bool} \] (ET15) \[ A \vdash q : \text{queue of } k \tau \quad A \vdash \text{full } q : \text{bool} \] (ET16) \[ A \vdash q : \text{queue of } k \tau \quad A \vdash \text{first } q : \tau \] (ET17)

\[ A \vdash q : \text{queue of } k \tau \quad A \vdash \text{dequeue } q : \text{queue of } k \tau \] (ET18) \[ A \vdash q : \text{queue of } k \tau \quad A \vdash \text{enqueue } (q, E) : \text{queue of } k \tau \] (ET19)
Access

\[
A(X) = \{\tau\} \quad \text{(ET20)} \quad \{\text{read}, \tau\} \subseteq A(X) \quad \text{(ET21)}
\]

\[
A \vdash X : \tau \\
A \vdash P : \text{array of } k \ \tau \\
A \vdash E : \text{interval } 0..k-1 \\
A \vdash P[E] : \tau \\
A \vdash P : \text{record } . . . , f : \tau, . . . \end{array} \quad \text{(ET22)}
\]

\[
A \vdash X : \tau \\
A \vdash P : \tau \quad \text{(ET23)}
\]

Global variables in write-only mode may not be read.

3.2.4 Typing patterns

By “pattern”, we mean the left hand sides of assignment statements, or the tuples of variables following “?” in input communication statements.

When used as arguments of some primitive, types of values can be promoted to any of their supertypes (by the use of the subsumption rule), but we want variables of all kinds to only store values of their declared type, and not of larger types. For this reason, patterns cannot be typed like expression.

As an illustrative example, assume variable \( X \) was declared with type \( \text{nat} \), and array \( A \) with type \( \text{array of } 16 \ \text{int} \). If lhs of assignments were given types by \( \vdash \), then the statement \( X := A[2] \) would be well typed, storing an integer where a natural is expected, since the rhs has type \( \text{int} \), and the lhs has type \( \text{nat} \), and \( \text{nat} \) is a subtype of \( \text{int} \).

Patterns are given types instead by specific relation \( (:p) \), defined by the following five rules. These rules are similar to those for \( (:) \) for variable and access expressions except that subsumption is restricted:

\[
A(X) = \{\tau\} \quad \text{(LT1)} \quad \{\text{write}, \tau\} \subseteq A(X) \quad \text{(LT2)}
\]

\[
A \vdash P : p \ \text{array of } k \ \tau \\
A \vdash E : \text{interval } 0..k-1 \\
A \vdash P[E] : \tau \\
A \vdash P : p \ \text{record } . . . , f : \tau, . . . \end{array} \quad \text{(LT3)}
\]

\[
A \vdash P : p \ f : \tau \\
A \vdash P : p \ f : \tau \quad \text{(LT4)}
\]

Global variables in read-only mode cannot be assigned.

3.2.5 Typing statements, well typed processes

Well-typing of the statement captured in a transition ensures two properties:

(a) That variables and expressions occurring in the transitions are well-typed and used consistently;
(b) That at most one communication occurs along any possible end-to-end control path in the
statement;

(c) That no shared variable is read or written along any end-to-end control path holding a com-

munication;

As for expressions, some information is inferred for statements, assuming a typing context; the
“typing” relation for statements is written \((:s)\); the “types” derived are subsets \(\alpha\) of \(\{\text{Shm, Com}\}\). Presence of \text{Shm} means that shared storage is manipulated along some control path not performing
any communication, presence of \text{Com} means that some control path performs a (single) commu-

nication but does not read nor writes shared variables. Note that a statement type may hold both
\text{Shm} and \text{Com}.

A process is well-typed if all of its transitions are well-typed in the typing context obtained from
its port declarations, formal parameter declarations and local variable declarations. A transition is
well typed if the statement it is defined from is well-typed. A statement \(S\) is well typed if one can
infer \(S :s \alpha\), for some \(\alpha \subseteq \{\text{Shm, Com}\}\), according to the following rules.

The rules make use of an auxiliary predicate \(Q_A(E)\), holding iff some shared variable occurs in
expression \(E\) in context \(A\), and of a “conditional” notation \(b \rightarrow \alpha | \beta\), standing for \(\alpha\) when \(b\) holds,
or for \(\beta\) otherwise.

Jump, \text{null}

\[
\begin{align*}
A \vdash \text{to } s :s \emptyset & \quad \text{(ST1)} \\
A \vdash \text{null } s :s \emptyset & \quad \text{(ST2)}
\end{align*}
\]

Sequential composition

\[
\begin{align*}
A \vdash S_1 &:s \emptyset & A \vdash S_2 :s \alpha & \quad \text{(ST3)} \\
A \vdash (S_1; S_2) :s \alpha & A \vdash S_1 :s \alpha & A \vdash S_2 :s \emptyset & \quad \text{(ST4)}
\end{align*}
\]

\[
A \vdash S_1 :s \{\text{Shm}\} & A \vdash S_2 :s \{\text{Shm}\}
\]

\[
\begin{align*}
A \vdash (S_1; S_2) &:s \{\text{Shm}\} & A \vdash S_1 &:s \{\text{Shm}\} & A \vdash S_2 &:s \{\text{Shm}\}
\end{align*}
\]

Assignments

\[
\begin{align*}
A \vdash P_1 :p \tau_1 & \ldots & A \vdash P_n :p \tau_n & A \vdash E_1 :\tau_1 & \ldots & A \vdash E_n :\tau_n & \quad \text{(ST6)}
\end{align*}
\]

\[
A \vdash P_1, \ldots, P_n := E_1, \ldots, E_n :s & \forall i \in 1..n (Q_A(P_i) \lor Q_A(E_i)) \rightarrow \{\text{Shm}\} | \emptyset
\]

\[
A \vdash P_1 :p \tau_1 & \ldots & A \vdash P_n :p \tau_n & A \vdash E :\text{bool}
\]

\[
A \vdash P_1, \ldots, P_n := \text{any where } E :s & \forall i \in 1..n Q_A(P_i) \lor Q_A(E) \rightarrow \{\text{Shm}\} | \emptyset
\]

Choices and while loop

\[
A \vdash E :\text{bool} & A \vdash S_1 :s \alpha & A \vdash S_2 :s \beta & Q_A(E) \Rightarrow \alpha \cup \beta \subseteq \{\text{Shm}\}
\]

\[
A \vdash \text{if } E \text{ then } S_1 \text{ else } S_2 \text{ end } :s \alpha \cup \beta
\]

\[
A \vdash E :\text{bool} & A \vdash S :s \alpha & \text{Com} \notin \alpha
\]

\[
A \vdash \text{while } E \text{ do } S \text{ end } :s Q_A(E) \rightarrow \{\text{Shm}\} | \alpha
\]

14
\[ A \vdash S_1 : \alpha_1 \ldots A \vdash S_n : \alpha_n \]
\[ A \vdash \text{select } S_1 [\ldots] S_n \text{ end } : \alpha_1 \cup \ldots \cup \alpha_n \quad (\text{ST10}) \]

If \( e \) then \( s \) end is handled like if \( e \) then \( s \) else null end. elsif is handled like else if.

Communications

\( \pi \) and \( \pi' \) are profiles (profile none or products \( \tau_1 \ast \cdots \ast \tau_n \) of types). Relation \( \leq \) is extended to profiles as explained in Section 3.2.2.

\[
\text{none} \in A(p) \quad \frac{}{A \vdash p \left[ ': \pi \right] : \mathcal{S} \{\text{Com}\}}(\text{ST11})
\]

\[
A \vdash E_1 : \tau_1 \ldots A \vdash E_n : \tau_n \quad \neg(\forall i \in 1..n(Q_A(E_i)))
\]
\[
\{\text{out}, \tau_1 \ast \cdots \ast \tau_n \} \subseteq A(p) \quad [\tau_1 \ast \cdots \ast \tau_n \leq \pi]
\]
\[
A \vdash p \left[ ': \pi \right] ! E_1, \ldots, E_n : \mathcal{S} \{\text{Com}\} \quad (\text{ST12})
\]

\[
A \vdash X_1 : p \tau_1 \ldots A \vdash X_n : p \tau_n \quad A \vdash E : \text{bool} \quad \neg(\forall i \in 1..n(Q_A(X_i)) \lor Q_A(E))
\]
\[
\{\text{in}, \pi'\} \subseteq A(p) \quad \pi' \leq \tau_1 \ast \cdots \ast \tau_n \quad [\pi' \leq \pi]
\]
\[
A \vdash p \left[ ': \pi \right] ? X_1, \ldots, X_n \quad \text{where } E : \mathcal{S} \{\text{Com}\} \quad (\text{ST13})
\]

- In an output communication, the profile of the values sent must be a subtype of some profile assigned to the port.
- In an input communication, some profile assigned to the port must be a subtype of the types of the variables assigned.
- When several profiles are assigned to a port in the port declarations of a process, it must be ensured that each occurrence of that port in the body of the process may be nonambiguously assigned one of these profiles. It is the user’s responsibility to solve ambiguities, by ascribing profile constraint(s) to some port occurrences. The profile constraint at some occurrence of a port restricts the profiles of that occurrence of the port to those which are subtypes of the constraint.

3.2.6 Well typed components

Components are checked in a context made of:

- A typing context \( A \), defined as for processes except that locally declared variables all have attributes read and write;

- An interface context \( I \), that associates with all previously declared processes and components an interface of shape \((\ldots, \mu_i, \ldots), (\ldots, \eta_j, \ldots)\) in which \( \mu_i \) is the set of attributes and profiles of the \( i^{th} \) port declared for the process or component, and \( \eta_j \) is the set of attributes and type of the \( j^{th} \) formal parameter of the component.
The expressions occurring in components are given types and attributes by relation :\_x, defined by:

\[
\frac{A(X) = \eta}{A, I \vdash X : x \eta} \quad (\text{CT1}) \quad \frac{A \vdash E : \tau \quad (E \text{ not a variable})}{A, I \vdash E : x \{\tau\}} \quad (\text{CT2})
\]

A component is well-typed if \textit{ok} can be inferred for it by relation :\_c, defined as follows:

\[
\frac{A, I \vdash c_1 : c \text{ ok} \quad \ldots \quad A, I \vdash c_n : c \text{ ok}}{A, I \vdash \text{shuffle } c_1, \ldots, c_n \text{ end } : c \text{ ok}} \quad (\text{CT3}) \quad \frac{A, I \vdash c_1 : c \text{ ok} \quad \ldots \quad A, I \vdash c_n : c \text{ ok}}{A, I \vdash \text{sync } c_1, \ldots, c_n \text{ end } : c \text{ ok}} \quad (\text{CT4})
\]

\[
\frac{A, I \vdash c_1 : c \text{ ok} \quad \ldots \quad A, I \vdash c_n : c \text{ ok}}{A, I \vdash \text{par } Q_1 \rightarrow c_1, \ldots, Q_n \rightarrow c_n \text{ end } : c \text{ ok}} \quad (\text{CT5})
\]

For any component \(c\), \(\Sigma(c)\) is its sort. Intuitively, the sort of a component is the set of ports it may use, component sorts will be formally defined in Section 4.3.1.

\[
\frac{A \vdash e_1 : x_{\eta_1} \quad \ldots \quad A \vdash e_n : x_{\eta_n} \quad ((A(p_1), \ldots, A(p_n)), (\eta_1, \ldots, \eta_m)) \prec I(C)}{A, I \vdash C[p_1, \ldots, p_n] (e_1, \ldots, e_m) : c \text{ ok}} \quad (\text{CT6})
\]

Where \(((\mu_{11}^1, \ldots, \mu_{n_1}^1), (\eta_{11}^1, \ldots, \eta_{m_1}^1)) \prec ((\mu_{12}^2, \ldots, \mu_{n_2}^2), (\eta_{12}^2, \ldots, \eta_{m_2}^2))\) holds iff:

- \(n_1 = n_2\) and for each \(i\):
  \(\mu_i^2 \subseteq \mu_i^1 \wedge \mu_i^1 - \mu_i^2 \subseteq \{\text{in, out}\}\)
- \(m_1 = m_2\) and for each \(j\):
  if \(\{\text{read, write}\} \cap \eta_j^2 \neq \emptyset\) then \(\eta_j^2 \subseteq \eta_j^1\) else \(\tau_j^1 \leq \tau_j^2\) where \(\eta_j^1 = \{\tau_j^1\}\) and \(\eta_j^2 = \{\tau_j^2\}\)

3.2.7 Well typed programs

A program is well typed if the declarations and component instance it contains are well typed.
4 Timed operational semantics

All programs in this section are assumed well-formed and well-typed.

4.1 Semantics of expressions

4.1.1 Semantic domains

The semantics of expressions is given in denotational style, it associates with every well-typed expression a value in some mathematical domain $D$ built as follows.

Let $\mathbb{Z}$ and $\mathbb{N}$ be the set of integers and non-negative integers, respectively, equipped with their usual arithmetic and comparison functions;

$\mathbb{B} = \{true, false\}$ be a domain of truth values, equipped with functions not, and and or;

$S$ be the set of strings containing letters, digits, and symbol ’‘;

$Arrays(E)$ be the set of mappings from finite subsets of $\mathbb{N}$ to $E$;

$Records(E)$ be set of mappings from finite subsets of $S$ to $E$;

Then $D = D_\omega$, where:

$D_0 = \mathbb{Z} \cup \mathbb{B} \cup S$

$D_{n+1} = D_n \cup Arrays(D_n) \cup Records(D_n)$

Fiacre arithmetic expressions are given meanings in set $\mathbb{Z}$, boolean expressions in set $\mathbb{B}$, enum expressions in $S$, arrays in some set $Arrays(D_n)$, and records in some set $Records(D_n)$, for some finite $n$. Queues denote some elements of $Arrays(D_n)$. The following mappings are defined for queue denotations ($D(m)$ is the domain of mapping $m$):

- empty $q$ is equal to true if $D(q) = \emptyset$, or false otherwise;
- full $k \ q \ (n \in \mathbb{N})$ is equal to true if $k - 1 \in D(q)$, or false otherwise;
- first $q = q(0)$, assuming $0 \in D(q)$;
- dequeue $q$, assuming $0 \in D(q)$, is the mapping $q'$ such that $q'(x - 1) = q(x)$ for all $x \in D(q)$;
- enqueue $q \ e$ is the mapping $q'$ such that $q'(x) = q(x)$ for $x \in D(q)$, and $q'(a) = e$, where $a$ is the smallest non negative integer not in $D(q)$.

4.1.2 Stores

Expression are given meanings relative to a store. The store associates values in $D$ with (some) variables. Stores are written $e$, $e'$, etc, $e(x)$ is the value associated with variable $x$ in store $e$, $D(e)$ is the domain of $e$. Entries are dynamically added to the store when non-initialized variables, or some of their components, are first assigned. The static condition in Section 3.1.3 ensures that variables or variable components are initialized before their first access.
4.1.3  Semantic rules for expressions

Evaluation rules all have the following shape. The rule means that, under conditions $P_1$ to $P_n$, the semantics of expression $E$ with store $e$ is $v$. The store $e$ may be omitted if the result does not depend on its contents.

$$\frac{P_1 \ldots P_n}{e \vdash E \leadsto v}$$

**Literals, initializers**

- Numeric constants denote integers in $\mathbb{Z}$. Implementations may choose to reject literals that are not machine representable;
- Enum values denote strings in $\mathcal{S}$;
- The booleans `true` and `false` denote values `true` and `false` in $\mathcal{B}$, respectively;
- `new n \tau` (any empty queue) denotes $\emptyset$;
- Representing mappings by their graphs, constant records and arrays are given meanings by:

$$\frac{\vdash l_1 \leadsto v_1 \ldots \vdash l_n \leadsto v_n}{\vdash [l_1, \ldots, l_n] \leadsto \{(0, v_1), \ldots, (n - 1, v_n)\}} \quad \text{(ES1)}$$

$$\frac{\vdash l_1 \leadsto v_1 \ldots \vdash l_n \leadsto v_n}{\vdash \{f_1 : l_1, \ldots, f_n : l_n\} \leadsto \{(f_1, v_1), \ldots, (f_n, v_n)\}} \quad \text{(ES2)}$$

**Access expressions**

$$\frac{X \in \mathcal{D}(e)}{e \vdash X \leadsto e(X)} \quad \frac{e \vdash P \leadsto a}{e \vdash P[E] \leadsto a(i)} \quad \frac{i \in \mathcal{D}(a)}{e \vdash P \leadsto i} \quad \frac{f \in \mathcal{D}(r)}{e \vdash P \leadsto r(f)} \quad \text{(ES4)} \quad \text{(ES5)}$$

Well-typing ensures that array indices cannot be out of range, nor fields undefined in the records they are sought for. Non initialized or partially initialized variables are not in the stores, hence the condition on domains. Satisfaction of these conditions is guaranteed by the static semantic constraints explained in Section 3.1.3.

**Primitives**

Well-typing implies that all primitives in an expression can be assigned at least one type. When several types can be assigned to some primitive, the typechecker is assumed to have computed a suitable one for it, typically the type that puts the weakest constraints on the arguments of the primitive.

The primitives whose semantics is type-dependent appear in the semantic rules with some annotations added (by the typechecker): arithmetic primitives are annotated with the type of their arguments, and some operators for queues are annotated with the length of the queue they are applied to.
Some primitives are partially defined (e.g. arithmetic functions over intervals, or taking an element from a queue). This appears in the rules by some extra hypothesis (side-conditions). The rules do not make precise any exception handling mechanism, it is assumed that implementations are able to detect when a rule is not applicable and take an adequate decision in that case.

- Arithmetic primitives at type $\tau$ ($\tau$ is some subtype of $\text{int}$):

$$
\frac{e \vdash x \rightsquigarrow a}{e \vdash -_\tau x \rightsquigarrow -a} \quad (\text{ES6}) \quad 
\frac{e \vdash x \rightsquigarrow a \quad e \vdash y \rightsquigarrow b}{e \vdash x @_\tau y \rightsquigarrow a @ b} \quad (\text{ES7})
$$

$$
\frac{e \vdash x \rightsquigarrow a \quad e \vdash y \rightsquigarrow b \quad b \neq 0}{e \vdash x @_\tau y \rightsquigarrow a @ b} \quad (\text{ES8})
$$

Operations over $\text{nat}$ or $\text{interval}$ types behave like those over $\text{int}$ type except that they are undefined if the result is not in the expected set. Predicate $\text{In}$ is defined as follows: $\text{In}(v, \text{int})$ always holds, $\text{In}(v, \text{nat})$ holds if $v \geq 0$, and $\text{In}(v, \text{interval } a..b)$ if $a \leq v \leq b$. Implementations may strengthen predicate $\text{In}$ by conditions asserting that the results are machine representable.

- Boolean primitives:

$$
\frac{e \vdash x \rightsquigarrow a}{e \vdash \text{not } x \rightsquigarrow \text{not } a} \quad (\text{ES10}) \quad e \vdash x \text{ and } y \rightsquigarrow a \text{ and } b \quad (\text{ES11})
$$

$$
\frac{e \vdash x \text{ or } y \rightsquigarrow a \text{ or } b}{e \vdash x @_\tau y \rightsquigarrow \text{true}} \quad (\text{ES13}) \quad e \vdash x @_\tau y \rightsquigarrow \text{false} \quad (\text{ES14})
$$

- Comparison and equality ($@ \in \{<, >, <=, >=, =, <>\}$):

$$
\frac{e \vdash x \rightsquigarrow a \quad e \vdash x \rightsquigarrow b \quad a @ b}{e \vdash x @ y \rightsquigarrow \text{true}} \quad (\text{ES13}) \quad e \vdash x @ y \rightsquigarrow \text{false} \quad (\text{ES14})
$$

- Primitives for queues:

$$
\frac{e \vdash q \rightsquigarrow Q}{e \vdash \text{empty } q \rightsquigarrow \text{empty } Q} \quad (\text{ES15}) \quad e \vdash q \rightsquigarrow Q \quad (\text{ES16})
$$

$$
\frac{e \vdash q \rightsquigarrow Q \quad \mathcal{D}(Q) \neq \emptyset}{e \vdash \text{first } q \rightsquigarrow \text{first } Q} \quad (\text{ES17})
$$

$$
\frac{e \vdash q \rightsquigarrow Q \quad \mathcal{D}(Q) \neq \emptyset}{e \vdash \text{dequeue } q \rightsquigarrow \text{dequeue } Q} \quad (\text{ES18}) \quad e \vdash q \rightsquigarrow Q \quad e \vdash x \rightsquigarrow v \quad N - 1 \notin \mathcal{D}(Q) \quad (\text{ES19})
$$

Note that $\text{first}$ and $\text{dequeue}$ are undefined on empty queues and that $\text{enqueue}_N$ is undefined on queues already holding $N$ elements.
4.1.4 Accesses in left-hand sides of assignments (L-values)

Left-hand sides of assignments evaluate to pairs \( z, g \), in which \( z \) is a value and \( g \) maps values to stores. Intuitively, \( g(v) \), where \( v \) is the value put into the location referred to by the lhs, is the updated store; \( z \) at some level is a partial value used to compute function \( g \) at the level above.

The evaluation relation for lhs of assignments is denoted \( \rightsquigarrow \) and defined by the following rules, in which:

- \( (\lambda v. f(v)) \) is the mapping that, applied to value \( v \), returns the value mapped by \( f \) to \( v \);
- \( \text{extend } f \ x = f \ x \) if \( x \in D(f) \), or \( \emptyset \) otherwise;
- \([x_1 \mapsto v_1, \ldots, x_n \mapsto v_n] \oplus e \) is the function \( f \) such that \( f(x_i) = v_i \) for any \( i \in 1..n \), and \( f(z) = e(z) \) for any \( z \in D(e) - \{x_1, \ldots, x_n\} \).

\[
\begin{align*}
\Gamma \vdash X \rightsquigarrow (\text{extend } e \ X), (\lambda v. [X \mapsto v] \oplus e) & \quad (LS1) \\
\Gamma \vdash P \rightsquigarrow e', a & \quad \Gamma \vdash E \rightsquigarrow i & \\
\frac{\Gamma \vdash P[E] \rightsquigarrow (\text{extend } e' \ i), (\lambda v. a([i \mapsto v] \oplus e'))}{(LS2)} \\
\Gamma \vdash P \rightsquigarrow e', r & \\
\frac{\Gamma \vdash P. f \rightsquigarrow (\text{extend } e' \ f), (\lambda v. r([f \mapsto v] \oplus e'))}{(LS3)}
\end{align*}
\]

4.2 Semantics of Processes

4.2.1 Notations

The semantics of transitions is expressed by a labelled relation, called the micro-step relation. Micro steps have shape \( (S, e) \xrightarrow{l} (S', e') \) in which \( S, S' \) are statements and \( e, e' \) are stores. Action \( l \) is either a communication action or the silent action \( \epsilon \). Communication actions are sequences \( p_r \ v_1 \ldots v_n \), in which \( p_r \) is a port, identified by a label and a profile, and the \( v_i \) are values.

4.2.2 Rules, micro-steps

The micro-step relation is defined inductively from the structure of statements by a set of inference rules. Each micro-step rule \( (S, e) \xrightarrow{l} (S', e') \) obeys the invariant \( S' \in \{\text{done}\} \cup \{\text{target } s | s \in \Lambda\} \), where \( \Lambda \) is the declared set of states of the process.

From, to, null

\[
\begin{align*}
(S, e) & \xrightarrow{l} (S', e') & (SS1) \\
(\text{from } s \ S, e) & \xrightarrow{l} (S', e') & (SS2) \\
(\text{null}, e) & \xrightarrow{l} (\text{done}, e) & (SS3) \\
(\text{to } s, e) & \xrightarrow{l} (\text{target } s, e)
\end{align*}
\]

20
Deterministic assignment
\[
e \vdash E_1 \rightsquigarrow v_1 \quad e \vdash E_2 \rightsquigarrow v_2 \quad \ldots \quad e \vdash E_n \rightsquigarrow v_n
\]
\[
e \vdash P_1 \rightsquigarrow^l e_1, a_1 \quad a_1(v_1) \vdash P_2 \rightsquigarrow^l e_2, a_2 \quad \ldots \quad a_{n-1}(v_{n-1}) \vdash P_n \rightsquigarrow^l e_n, a_n
\]
\[
e' = a_n(v_n)
\]
(\(P_1, P_2, \ldots, P_n := E_1, E_2, \ldots, E_n, e\) \(\Rightarrow\) (\(\text{done}, e'\))) \hspace{1cm} (SS4)

The independence property for accesses in multiple assignments, enforced by the static semantic constraint in Section 3.1.2, ensures that the resulting store is invariant by any permutation of accesses \(P_1, \ldots, P_n\) and the corresponding expressions \(E_1, \ldots, E_n\).

Nondeterministic assignment
\[
e \vdash P_1 \rightsquigarrow^l e_1, a_1 \quad a_1(v_1) \vdash P_2 \rightsquigarrow^l e_2, a_2 \quad \ldots \quad a_{n-1}(v_{n-1}) \vdash P_n \rightsquigarrow^l e_n, a_n
\]
\[
e' \vdash E \rightsquigarrow \text{true} \quad e' = a_n(v_n)
\]
(\(P_1, P_2, \ldots, P_n := \text{any where } E, e\) \(\Rightarrow\) (\(\text{done}, e'\))) \hspace{1cm} (SS5)

\(v_i\) ranges over all values of the type of \(P_i\).

While loops
\[
e \vdash E \rightsquigarrow \text{true} \quad (S; \text{while } E \text{ do } S \text{ end}, e) \xrightarrow{l} (S', e') \hspace{1cm} (SS6)
\]
\[
(\text{while } E \text{ do } S \text{ end}, e) \xrightarrow{l} (S', e')
\]
\[
(\text{while } E \text{ do } S \text{ end}, e) \xrightarrow{s} (\text{done}, e)
\]
(\(SS7\))

It is assumed that condition \(E\) eventually evaluates to false.

Deterministic choice
\[
e \vdash E \rightsquigarrow \text{true} \quad (S_1, e) \xrightarrow{l} (S, e') \hspace{1cm} (SS8)
\]
\[
e, E \rightsquigarrow \text{false} \quad (S_2, e) \xrightarrow{l} (S, e') \hspace{1cm} (SS9)
\]

if \(e\) then \(S_1\) else \(S_2\) end is handled like if \(e\) then \(S\) else null end. elsif is handled like else if.

Nondeterministic choice
\[
(\exists i \in 1..n)((S_i, e) \xrightarrow{l} (S_i', e'))
\]
(\(SS10\))

(\(\text{select } S_1 [ ] \ldots [ ] S_n \text{ end}, e\) \(\xrightarrow{l}\) (\(S_i', e'\))

Sequential composition
\[
(S_1, e) \xrightarrow{l} (\text{target } s, e') \hspace{1cm} (SS11)
\]
\[
(S_1; S_2, e) \xrightarrow{l} (\text{target } s, e') \hspace{1cm} (SS12)
\]
with “.” such that \(\epsilon.\epsilon = \epsilon\) and \(\epsilon.l = l.\epsilon = l\), for any \(l\).

The well-formedness condition implies \(l_1 = \epsilon \lor l_2 = \epsilon\).

Note that the statements following a to statement are dead code.
Communication

\[(p_r, e) \xrightarrow{p_r} (\text{done}, e)\]  
(SS13)

\[e \vdash E_1 \rightsquigarrow v_1 \quad \ldots \quad e \vdash E_n \rightsquigarrow v_n\]  
(SS14)

\[e' = e[X_1 \mapsto v_1, \ldots, X_n \mapsto v_n] \quad [e' \vdash E \rightsquigarrow \text{true}]\]  
(SS15)

Types decorate ports to distinguish the different variants of overloaded ports.  
\(v_i\) ranges over all values of the type of \(X_i\).

4.2.3 Macro-steps

By the previous rules, Fiacre transitions expand into series of micro-steps originating at the process state specified by the from statement, and ending at some target process state specified in a to statement. Each of these sequences identifies a possible discrete macro-step, or process action, as follows. The semantics of a process is the union of the action relations of all its transitions.

\[\frac{\text{(from } s S, e)}{(s, e) \xrightarrow{L} (s', e')}\]

A process configuration is a pair constituted of a process state and a store capturing the values of its initialized local variables. Note that shared variables are not considered part of process configurations, intuitively, configurations characterize the local state information for the process.

The initial configuration of a process is the pair \((s_0, e_0)\) in which \(s_0\) is the declared initial state of the process and store \(e_0\) captures the values of the formal parameters of the process and those of its statically initialized local variables.

4.3 Semantics of programs and components

A program is a series of declarations followed by component identifier or a closed component instance. The semantics of a program is the semantics of that component or component instance.

4.3.1 Component states, terminology

Labels, ports: Let us recall a communication action is either the silent action \(\epsilon\) or a sequence \(p_r \; v_1 \ldots \; v_n\), in which \(p_r\) is a port with label \(p\) and profile \(\pi\), and the \(v_i\) are values. If \(l \neq \epsilon\), then \(L(l)\) denotes the port used in action \(l\).

Component states: Component states are abstract terms built from the following grammar:
\[ c \ ::= \ c_1 | c_2 \quad \text{product} \]
\[ \text{hide } H I \ c \quad \text{hiding, } H \text{ is a set of ports and } I \text{ maps them to time intervals} \]
\[ \text{relab } R \ c \quad \text{relabelling, } R \text{ is a surjective mapping over ports} \]
\[ \text{prio } \Pi I \ c \quad \text{priority assignment, } \Pi \text{ is a priority relation between ports} \]
\[ \text{proc } P (s, e) \quad \text{process call, } P \text{ is a process identifier, } (s, e) \text{ a process configuration} \]
\[ \text{comp } C \ c \quad \text{component call, } C \text{ is a component identifier, } c \text{ a component state} \]

For simplifying the semantics rules, all composition operators will be expressed in terms of relabelling and a binary product written \( "|" \). \( "|" \) denotes the usual product for timed transition systems. Equivalence of compositions will be briefly addressed in Section 4.4.

**Process and component sorts:** The sort of a named process \( P \) or named component \( C \), written \( \Sigma(P) \) or \( \Sigma(C) \), is the set of visible ports declared for that process or component. If some port \( p \) has several profiles \( \pi_1, \ldots, \pi_n \) declared, then the overloaded port appears in the sort as several ports \( p_{\pi_1}, \ldots, p_{\pi_n} \) with the same label but different profiles. The notion of sort is extended to component states as follows:

\[
\begin{align*}
\Sigma(c_1 | c_2) &= \Sigma(c_1) \cup \Sigma(c_2) \\
\Sigma(\text{hide } H I \ c) &= \Sigma(c) - H \\
\Sigma(\text{relab } R \ c) &= \{R(p_{\tau}) \mid p_{\tau} \in \Sigma(c) \cap D(R)\} \cup (\Sigma(c) - D(R)) \\
\Sigma(\text{prio } \Pi I \ c) &= \Sigma(c) \\
\Sigma(\text{proc } P (s_0, e_0)) &= \Sigma(P) \\
\Sigma(\text{comp } C \ c) &= \Sigma(C)
\end{align*}
\]

Note that the sort of a named component \( C \), defined from its declared list of ports, may differ from the sort one could compute from its body (for instance because some port declared in the component parameters does not occur in its body nor in that of all components invoked from it). Similarly, process headers may introduce ports never used in the process body.

**Initial state of a component:** The initial state of a component is the result of its rewriting by relation \( \rightsquigarrow_0 \), defined in the sequel. Intuitively, \( \rightsquigarrow_0 \) “inlines” component definitions, keeping track of component boundaries for preserving the sorts of subcomponents, and replaces process definitions by their initial configurations. Relation \( \rightsquigarrow_0 \) is defined by the following rules:

\[
\begin{align*}
(\text{shuffle } c_1 \ldots c_n \text{ end}) & \quad \text{is handled like } (\text{par } \rightarrow c_1 \ldots \rightarrow c_n \text{ end}) \\
\quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad
\end{align*}
\]

where

\[
A = \bigcup_{i \in \{1, \ldots, n\}} \Sigma(c_i)
\]

\( B \) is some set of ports disjoint from \( A \)

\( \Psi \) is some bijection from \( A \) to \( B \)

\( R_i \) is \( \Psi \) restricted to the domain \( \Sigma(c_i) - s_i \)
\[ R = \Psi^{-1} \]

\[
(\forall i \in F)(e \vdash e_i \rightsquigarrow v_i) \quad e \oplus \{ x_i \mapsto v_i \mid i \in F \} \oplus a \vdash c \rightsquigarrow_0 c'
\]

\[ e \vdash C \quad [q_i]_{i \in E} \quad (\forall i \in F) \quad (e \vdash e_i \rightsquigarrow v_i) \quad e \oplus \{ x_i \mapsto v_i \mid i \in F \} \oplus a \vdash c \rightsquigarrow_0 c' \]

\[
\begin{align*}
C & \text{ is the name of a component expecting as parameters ports } p_i \text{ and variables } x_i, \text{ and of body } c. \text{ Store } a \text{ captures the variables locally declared and statically initialized in } C, \text{ } H \text{ maps time intervals to them (default } [0, \infty]). \\
\text{Without loss of generality, it is assumed that the non-shared } x_i \text{ and the variables locally declared in } C \text{ have different names than those of all variables in store } e, \text{ and that the names of the shared } x_i \text{ match the names of the variables in } e \text{ they are bound to. } \Pi \text{ is the priority relation defined in } C, \text{ that is the transitive closure of the port pairs occurring in the priority declarations, if any; } (p_r,q_{r'}) \in \Pi \text{ means that communication actions over port } p_r \text{ have higher priority than those over port } q_{r'}. \\
\end{align*}
\]

\[
(\forall i \in F)(e \vdash e_i \rightsquigarrow v_i) \quad e \vdash P \quad [q_i]_{i \in E} \quad (\forall i \in F) \quad (e \vdash e_i \rightsquigarrow v_i) \quad (\text{proc } P \quad (s_0, \{ x_i \mapsto v_i \mid i \in F^p \} \oplus a))
\]

\[
\begin{align*}
P & \text{ is the name of a process expecting as parameters ports } p_i \text{ and variables } x_i, \text{ with initial state } s_0. \text{ } F^p \text{ is the subset of } F \text{ corresponding to the parameters passed to } P \text{ “by value” (excluding the shared variable parameters); store } a \text{ captures the variables locally declared and statically initialized in } P. \text{ } (s_0,e_0), \text{ where } e_0 = \{ x_i \mapsto v_i \mid i \in F^p \} \oplus a \text{ is the initial configuration of the process. As for component instances, it is assumed without loss of generality that the non-shared } x_i \text{ and the variables locally declared in } P \text{ have different names than those of the variables in } e, \text{ and that the names of the shared } x_i \text{ match the names of the variables in } e \text{ they are bound to.}
\end{align*}
\]

4.3.2 Component interactions

Interactions are triples \((c,e,i)\) in which \(c\) is a component state, \(e\) is a store, and \(i\) an interaction label. Intuitively, the set of communication actions of a component is partitioned into interactions; two communication actions “matching” the same interaction will share their timing information.

Interaction labels are abstract terms built from the following grammar:

\[
\begin{align*}
k & ::= \bullet \quad \text{the silent interaction} \\
& \mid p_r \quad \text{port interactions} \\
& \mid \text{inl}(k) \mid \text{inr}(k) \quad \text{injection interactions} \\
& \mid (k_1,k_2) \quad \text{product interactions}
\end{align*}
\]

The interaction label \(\langle l \rangle\) associated with a process action \(l\) is defined by: \(\langle \epsilon \rangle = \bullet, (p_r,v \ldots v_n) = p_r\). Computation of component interaction labels will be explained with the semantic rules.

\(L(c,k)\) is the communication label of the actions of component \(c\) matching interaction label \(k\), if any. If no action matching \(k\) is visible, then \(L(c,k) = \emptyset\). \(L(c,k)\) is computed as follows:

24
\[ L(c, \bullet) = \emptyset \]
\[ L(c_1 \mid c_2, \text{inl}(k)) = L(c_1, k) \]
\[ L(c_1 \mid c_2, \text{inr}(k)) = L(c_2, k) \]
\[ L(c_1 \mid c_2, (k_1, k_2)) = L(c_1, k_1) \]
\[ L(\text{hide } H \mid c, k) = \begin{cases} \emptyset & \text{if } L(c, k) \in E \\ L(c, k) & \text{else} \end{cases} \]
\[ L(\text{relab } R \mid c, k) = \begin{cases} L(R(c, k)) & \text{if } L(c, k) \in \mathcal{D}(R) \\ L(c, k) & \text{else} \end{cases} \]
\[ L(\text{prio } \Pi \mid c, k) = L(c, k) \]
\[ L(\text{comp } C \mid c, k) = L(c, k) \]
\[ L(\text{proc } P \mid (s_0, e_0), k) = k \]

### 4.3.3 Component configurations

Component configurations are triples \((c, e, \phi)\) in which \(c\) is a component state, as defined in Section 4.3.1, \(e\) is a store, and \(\phi\) is an interval function.

Function \(\phi\) maps the enabled interactions at the source configuration to the time intervals in which actions “matching” those interactions may occur. Since the source state and store are implicit, \(\phi\) simply maps interaction labels to time intervals; the set of interactions enabled at some configuration \((c, e, \phi)\) is the set of triples \(\{(c, e, i) \mid i \in \mathcal{D}(\phi)\}\).

The initial configuration of a component is the initial component state \(c_0\) resulting from its evaluation by \(\sim_0\), associated with the store constituted of all variables locally declared in the component and all component instances invoked in it (all variables declared are assumed to have different names, according to our convention Section 4.3.1), and the initial interval function \(\phi_0\).

\(\phi_0\) maps time intervals to the labels of the interactions corresponding to the actions enabled at the initial configuration of the component. It is defined as the result of applying function \(\Phi\) defined below to the initial component state and initial store. Function \(\Phi\) is defined as follows:

\[ \Phi(\text{proc } P \mid (s_0, e_0), e) = \{(\emptyset, [0, \infty]) \mid (\exists s, e')(((s_0, e \oplus e_0) \downarrow (s, e'))\} \]
\[ \Phi(c_1 \mid c_2, e) = \Phi(c_1, e) \mid \Phi(c_2, e) \]
\[ \Phi(\text{hide } H \mid c, e) = \{(k, r) \in \phi \mid L(c, k) \not\in H\} \cup \{(k, I(L(c, k)) \in \phi \mid L(c, k) \in H\} \]
\[ \text{where } \phi = \Phi(c, e) \]
\[ \Phi(\text{relab } R \mid c, e) = \Phi(c, e) \]
\[ \Phi(\text{prio } \Pi \mid c, e) = \Phi(c, e) \]
\[ \Phi(\text{comp } C \mid c, e) = \Phi(c, e) \]

where

\[ \phi_1 \mid \phi_2 = \{(\text{inl}(k), r) \mid (k, r) \in \phi_1 \land L(c_1, k) \in \Sigma(c_1) - \Sigma(c_2)\} \]
\[ \cup \{(\text{inr}(k), r) \mid (k, r) \in \phi_2 \land L(c_2, k) \in \Sigma(c_2) - \Sigma(c_1)\} \]
\[ \cup \{(k_1, k_2, r) \mid (k_1, r) \in \phi_1 \land (k_2, r) \in \phi_2 \land L(c_1, k_1) = L(c_2, k_2) \land L(c_1, k_1) \in \Sigma(c_1) \cap \Sigma(c_2)\} \]

### 4.3.4 Semantic rules for components

The semantics of a component is a Timed Transition System. These are Labelled Transition Systems extended with state properties and time-elapsing transitions. The labelled semantics relation,
linking component configurations, has two sorts of transitions: discrete (communication actions) and continuous (real delays).

For making easier the definition of the transition relation, discrete transitions will be concretely labelled both with a communication action (above the arrow) and the corresponding interaction label (below the arrow), as shown in the sequel. Note that, in this formula, we always have \( l = \epsilon \) and \( L(c, k) = \bullet \), or otherwise \( L(l) = L(c, k) \).

\[
(c,e,\phi) \xrightarrow{l}{k} (c',e',\phi')
\]

Continuous transitions

\[
\frac{\forall k \,(\phi(k) \neq \bot \Rightarrow \theta \leq \uparrow \phi(k))}{(c,e,\phi) \Theta \rightarrow (c,e,\phi - \theta)}
\] (PS1)

Time may elapse as long as no time-constrained interaction passes its deadline.

For any interval \( r \), \( \uparrow r \) is its right endpoint, or \( \infty \) if \( r \) is not right-bounded.

For any \( k \): \[
(\phi - \theta)(k) = \{ x - \theta \mid (x - \theta) \geq 0 \land x \in \phi(k) \}
\]

Product

\[
(c_1,e,\phi_1) \xrightarrow{l}{k} (c'_1,e',\phi'_1) \quad l = \epsilon \lor L(l) \notin \Sigma(c_2)
\]

\[
(c_1|c_2,e,\phi_1|\phi_2) \xrightarrow{l}{k} (c'_1|c_2,e',\phi'_1|\phi'_2)
\] (PS2)

\[
(c_2,e,\phi_2) \xrightarrow{l}{k} (c'_2,e',\phi'_2) \quad l = \epsilon \lor L(l) \notin \Sigma(c_1)
\]

\[
(c_1|c_2,e,\phi_1|\phi_2) \xrightarrow{l}{k} (c_1|c'_2,e',\phi_1|\phi'_2)
\] (PS3)

\[
(c_1,e,\phi_1) \xrightarrow{l}{k} (c'_1,e,\phi'_1) \quad (c_2,e,\phi_2) \xrightarrow{l}{k} (c'_2,e,\phi'_2) \quad l \neq \epsilon
\]

\[
(c_1|c_2,e,\phi_1|\phi_2) \xrightarrow{l}{(k_1,k_2)} (c'_1|c'_2,e,\phi'_1|\phi'_2)
\] (PS4)

Hiding

\[
(c,e,\phi \ominus H) \xrightarrow{l}{k} (c',e',\phi') \quad l = \epsilon \lor L(l) \notin H
\]

\[
(hide \ H \ I \ c,e,\phi) \xrightarrow{l}{k} (hide \ H \ I \ c',e',\phi' \setminus \phi)
\] (PS5)

Discrete transition through hidden ports must be possible without additional delay. \( \phi \ominus H \) relaxes the intervals of the actions labelled in \( H \), \( \phi' \setminus \phi \) restores them for persistent actions, and initializes them for newly-enabled actions:
\[
(\phi \ominus H) = \{(k, r) \in \phi \mid L(c, k) \notin H\} \cup \{(k, [0, \infty]) \mid k \in D(\phi) \land L(c, k) \in H\}
\]
\[
(\phi' \ominus I \phi) = \{(k, r) \in \phi \mid k \in D(\phi')\} \cup \{(k, I(L(c, k))) \in \phi' \mid k \in D(\phi') \land D(\phi)\}
\]

Relabelling
\[
\begin{align*}
(c, e, \phi) & \xrightarrow{l} (c', e', \phi') \\
& \quad l = \epsilon \lor L(l) \notin D(R) \quad (PS7)
\end{align*}
\]

\[
\begin{align*}
(c, e, \phi) & \xrightarrow{p_{r, v_1} \ldots v_n} (c', e', \phi') \\
& \quad p_{r} \in D(R) \quad (PS8)
\end{align*}
\]

Priorities
\[
(c, e, \phi) \xrightarrow{l} (c', e', \phi') \\
& \quad l = \epsilon \lor (\forall l', k', b)(((c, e, \phi) \xrightarrow{v} b \land l' \neq \epsilon \Rightarrow (L(l'), L(l)) \notin \Pi) \quad (PS9)
\]

Priorities forbid a communication action to occur when some other communication labelled with a port with higher priority is possible. Remember that silent actions are never involved in priorities.

Component actions
\[
\begin{align*}
(c, e, \phi) & \xrightarrow{l} (c', e', \phi') \\
& \quad (PS10)
\end{align*}
\]

Process actions
\[
\begin{align*}
(s, e \oplus a) & \xrightarrow{l} (s', e' \oplus a') \\
\phi' & = \{(l'), [0, \infty] \mid (\exists s', e'((s, e \oplus a) \xrightarrow{v} (s', e'))\}\} \quad (PS11)
\end{align*}
\]

\[\langle l \rangle\] (see Section 4.3.2) is the process interaction associated with action \(l\). Function \(\phi'\) associates interval \([0, \infty]\) to all interactions associated with the actions enabled at process configuration \((s, e \oplus a)\). The transition above the line is a process macro-step, the transition below is a component step. From the variable naming hypotheses for component and process instances, (see Section 4.3.1), the store of a process instance can always be seen as partitionned into local variables with “new” names, and shared variables named as in the store \(e\) of the component.
4.4 Composition identities

Several composition operators have been provided to accomodate various specification styles, and more might be introduced in the future. For the purpose of formalizing their semantics, all these operators have been expressed in Section 4.3 in terms of rebalelling and product $|$, the usual synchronous product for timed transition systems. For specification purposes, composition operators enjoy some useful relationships, in particular:

\[
\begin{align*}
\text{shuffle } c_1 \ldots c_n \text{ end} & = \text{par} \to c_1 \ldots \to c_n \text{ end} \\
\text{sync } c_1 \ldots c_n \text{ end} & = \text{par} \Sigma(c_1) \to c_1 \ldots \Sigma(c_n) \to c_n \text{ end}
\end{align*}
\]
